

Project Outcome Report

UNICC AI Safety Lab: Governance-Aligned AI Evaluation Powered by a Council of Experts

Student Name: Shoa Afroz

Program: MS in Management and Analytics

School: New York University, School of Professional Studies

Course: Applied Technical Project

Instructor: Dr. Steven W. Goss

Project Sponsor: United Nations International Computing Centre (UNICC)

Project Guide / Sponsor Representative: Dr. Andrés Fortino, Clinical Associate Professor, NYU SPS

Project Focus: AI Safety Evaluation System, Testing, UI/UX, and Deployment Readiness

Submission Date: May 2026

1. Outcome Overview

The outcome of this applied technical project is a working AI Safety Evaluation prototype designed for the United Nations International Computing Centre (UNICC). The system operationalizes AI safety evaluation through a structured Council of Experts workflow that reviews AI systems before deployment and produces transparent, auditable, and governance-aligned outputs.

The project responds to a core organizational need: AI systems cannot be evaluated only through informal review or single-model judgment when they are being considered for use in governance-sensitive environments. UNICC requires an approach that supports trust, traceability, and informed decision-making before AI systems are adopted within the AI Sandbox or related institutional settings.

The outcome demonstrates how AI safety can be translated from a broad governance concept into an implementable workflow. The system allows a user to submit an AI system, trigger independent expert evaluations, review expert reasoning, observe deliberation between evaluators, and receive a final Council decision supported by confidence levels, cited reasoning, and audit evidence.

Council of Experts — AI Safety Lab

Submit an AI system (by GitHub URL or text description) for evaluation by three specialized experts: Risk & Technical Standards (NIST, ISO, OWASP, MITRE ATLAS), AI Safety & Red-Team (6-dimension adversarial assessment), and Governance & Regulatory (EU AI Act, UN, UNESCO).

The council follows a three-phase protocol: independent drafting → cross-expert deliberation → consensus synthesis.

The screenshot shows a web interface for submitting an AI system for evaluation. It is titled "Council of Experts — AI Safety Lab". Below the title, there is a brief description of the submission process and the experts involved. The main form is divided into two columns. The left column has a section "Input Type" with two radio buttons: "GitHub URL" (selected) and "Text Description". Below this is a text input field labeled "AI System to Evaluate" containing the URL "https://github.com/FlashCarrot/VeriMedia". The right column has a section "LLM Provider" with two radio buttons: "anthropic" and "groq" (selected). Below this is a text input field labeled "Anthropic API Key" containing "sk-ant-..." and another text input field labeled "Groq API Key" containing a series of asterisks. At the bottom right of the form is a large orange button labeled "Run Evaluation".

Figure 1. AI Safety Lab interface for submitting an AI system for Council of Experts evaluation.

2. Problem Addressed

The project addresses the lack of a structured, reproducible, and auditable process for evaluating AI systems before deployment. In many organizations, AI safety evaluation remains fragmented across manual reviews, isolated technical checks, or black-box model assessments. These approaches create several risks: limited transparency, inconsistent judgments, weak traceability, and difficulty explaining why an AI system was approved, flagged, or rejected.

For UNICC, this problem is especially important because AI systems may operate in high-stakes, cross-agency, and governance-sensitive environments. A deployable AI evaluation system must therefore support more than technical performance. It must also assess safety, bias, security, transparency, governance alignment, and institutional risk.

The project outcome directly connects to the original problem definition by creating a workflow that makes AI safety evaluation systematic, reviewable, and repeatable.

3. Final Solution

The final solution is a Council of Experts-based AI Safety Evaluation system. Instead of relying on one evaluator or one generic LLM judgment, the system uses three independent expert modules that review the same AI system from different but complementary perspectives:

Figure 2. Council of Experts structure showing independent expert evaluation modules.

Each expert produces an independent assessment, including a verdict, confidence level, reasoning, and relevant sources or framework references. After the independent evaluation stage, the system moves into a deliberation phase, where experts respond to one another's findings and refine their conclusions. The final step is a consensus synthesis that generates the overall Council decision.

The system produces structured outputs that are useful for both technical and non-technical stakeholders. Technical users can inspect expert reasoning and audit logs, while governance and management stakeholders can review the final decision, confidence level, and summarized risk findings.

Council Final Decision

Verdict: FLAG

Combined Confidence: 90%

Synthesized Rationale

The VeriMedia AI system, designed for media content analysis, raises significant concerns regarding data privacy and security, potential biases in its training data and models, lack of transparency in its decision-making processes, and vulnerabilities in its architecture and dependencies. While the system has potential for promoting ethical and accurate reporting, its current implementation requires careful scrutiny and mitigation of identified risks to ensure compliance with governance, safety, and ethical standards.

Points of Agreement

- The system's reliance on OpenAI's GPT-4o and Whisper API introduces potential risks related to data privacy and security.
- The training data's focus on sensitive topics and the use of potentially biased models are significant concerns.
- The system's architecture and dependencies may introduce vulnerabilities if not properly secured.
- The lack of transparency in the AI models and decision-making processes is a significant concern.
- The system's features, while notable, must be carefully evaluated to ensure they do not inadvertently perpetuate harmful content or biases.

Points of Dissent

- The potential benefits of the system in promoting ethical and accurate reporting, if properly implemented and mitigated.

4. How the Outcome Works

The evaluation workflow follows a structured sequence:

1. First, the user submits an AI system for review. The system can accept a GitHub repository URL or a written description of an AI system. For GitHub-based testing, the repository content is used as evidence for evaluation.
2. Second, the system sends the same input to three independent expert evaluators. Each expert assesses the system through its assigned lens and produces a structured safety judgment.

- Third, the system conducts a deliberation exchange. This step is important because it allows the expert modules to compare findings, surface disagreements, and refine their reasoning before the final decision is made.
- Fourth, the system generates a final Council decision. The final output includes the overall verdict, confidence level, reasoning summary, expert alignment, and key risks identified.
- Finally, the system preserves evaluation evidence through audit logs and structured output records. This ensures that the evaluation can be reviewed later instead of existing only as a one-time model response.

Figure 4. Deliberation exchange showing how expert modules respond to one another before final synthesis.

5. Implementation Evidence

The prototype was tested using the VeriMedia GitHub repository as the main AI safety test case. The Council of Experts produced FLAG decisions across all three expert modules, and the final Council decision was also FLAG with 90 percent combined confidence.

This result demonstrated that the system could identify meaningful safety and governance concerns while still recognizing potential system value. The FLAG outcome showed that the system was not simply approving or rejecting AI systems automatically, but supporting a more realistic governance decision: the system may be useful, but requires further review before deployment.

The evaluation identified issues connected to privacy, bias, transparency, and governance readiness. These are the types of risks that UNICC stakeholders would need to understand before moving an AI system closer to production use.

Figure 5. Final Council decision for the VeriMedia test case showing a FLAG verdict with 90% combined confidence.

6. Auditability and Traceability

A key value of the outcome is that it does not only generate a final verdict. It also preserves the reasoning path behind that verdict. The system creates an audit trail that captures the input, expert assessments, deliberation responses, final synthesis, timestamps, and evaluation metadata.

This is important for governance-sensitive environments because stakeholders need to understand how a decision was reached. A simple automated output is not enough when the decision may influence whether an AI system is safe to test, adopt, or deploy.

The audit log strengthens accountability by making the evaluation reviewable after the run is complete. It also supports repeatability because future evaluators can compare new results against previous outputs.

7. Stakeholder-Facing Reporting Layer

In addition to the Council of Experts workflow, the project includes a Streamlit dashboard that demonstrates how evaluation results can be presented in a more stakeholder-facing format. This dashboard supports repository submission, score visualization, downloadable JSON reports, and comparison across previous evaluation runs.

The Streamlit component adds value by showing how the same type of evaluation output could be translated into a more accessible reporting layer for managers, governance reviewers, and technical teams. It is especially useful for comparing runs and observing whether scores or verdicts change across repeated evaluations.

This part of the outcome supports adoption because different stakeholders need different levels of detail. Technical users may need expert reasoning and logs, while business or governance stakeholders may need summarized verdicts, scores, and comparison views.

Figure 8. Compare Runs feature showing score and verdict comparison across repeated evaluations.

8. Connection to Goals and Success Metrics

The project outcome connects directly to the original project goal: to design and implement a governance-aligned AI safety evaluation system that enables consistent, reproducible, and auditable assessment of AI outputs before deployment.

The outcome addresses the major success metrics as follows:

1. The system supports structured evaluation by using three defined expert modules and a clear Council workflow.
2. The system supports governance alignment by grounding evaluation in safety, risk, compliance, transparency, and human review considerations.
3. The system supports auditability through logs, structured outputs, timestamps, and preserved evaluation records.
4. The system supports reproducibility by allowing repeated test runs and comparison across outputs.
5. The system supports usability by presenting results through an interface that can be understood by both technical and non-technical stakeholders.
6. The system supports implementation readiness by demonstrating a working prototype, repository-based testing, final verdict generation, and stakeholder-facing reporting outputs.

9. Value to UNICC

The outcome provides clear value to UNICC because it offers a practical way to evaluate AI systems before they are moved closer to deployment. Instead of relying on informal judgment or a single automated model response, the system creates a structured review process that combines expert-style reasoning, deliberation, consensus, and audit evidence.

For UNICC, this type of tool can function as a pre-deployment safety gate within the AI Sandbox. It can help teams identify whether an AI system appears safe, needs further review, or should be rejected due to risk concerns. This supports better decision-making and reduces operational, reputational, and governance risk.

The system is also valuable because it translates research and governance theory into a working workflow. Concepts such as AI risk management, red-teaming, bias evaluation, compliance alignment, and auditability are embedded into the actual evaluation process rather than remaining as abstract principles.

10. Professional Readiness

This outcome is designed to be useful beyond the classroom because it resembles the type of applied solution organizations need when adopting AI responsibly. It combines product thinking, system design, risk analysis, user experience, and project management.

From a professional perspective, the project demonstrates the ability to:

- Translate an organizational problem into a working technical solution
- Define functional and governance requirements
- Build and test a prototype under real project constraints
- Use AI tools responsibly within a structured evaluation workflow
- Create stakeholder-facing outputs for decision-making
- Document evidence, risks, limitations, and future implementation needs

The project is not presented as a production-ready enterprise system. Instead, it is a professional-grade proof of concept that demonstrates feasibility and provides a strong foundation for future adoption, refinement, and integration into a controlled UNICC environment.

11. Limitations

The outcome has several limitations.

- SLM/LLM-assisted evaluations can vary across repeated runs, which means the system should not be used as a fully automated final authority. Human oversight remains necessary.
- The system was tested using selected repositories and controlled scenarios. Broader testing across more AI systems would be required before institutional deployment.
- The current prototype demonstrates workflow feasibility, reasoning structure, and reporting value, but further engineering work would be needed for production-grade access control, security hardening, model hosting, and integration with UNICC infrastructure.

These limitations do not reduce the value of the outcome. Instead, they clarify the appropriate use of the system as a pre-deployment decision-support tool rather than an autonomous approval mechanism.

12. Final Outcome Statement

The completed project outcome is a working AI Safety Evaluation prototype that demonstrates how UNICC can operationalize responsible AI review through a Council of Experts model. The system connects AI governance theory to a practical workflow by enabling structured input submission, independent expert evaluation, deliberation, final consensus, audit logging, and stakeholder-facing reporting.

The outcome shows that AI safety evaluation can be made more transparent, repeatable, and actionable when it is designed as a structured governance process rather than a single black-box judgment. It provides UNICC with a practical foundation for future AI Sandbox evaluation workflows and demonstrates readiness for continued refinement beyond the classroom.
